## 90-day entry plan

**Entry principle:** Earn the right to standardize by shipping with a client. Learn the actual delivery system before prescribing a universal one.

### DAYS 1-30 — READ THE ENVIRONMENT

| Objective                  | Actions                                                                                            | Evidence                                      |
|----------------------------|----------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Understand the FDE system  | Shadow an active pod; map sponsor, product/platform, ATC, security, data and production ownership. | Stakeholder/decision map and engagement flow. |
| Read one workflow deeply   | Observe users, exceptions, current controls and what the process protects.                         | Workflow boundary and exception inventory.    |
| Baseline release mechanics | Trace intake → prototype → evidence → approval → production → run ownership.                       | Current-state load path with friction points. |
| Build trust                | Contribute directly to workshops, code-with activity, evaluation cases and delivery routines.      | Accepted increments and explicit feedback.    |

### FIRST DELIVERABLES

One Agent Load Path review · one workflow-specific metric baseline · one bounded technical working session · one list of reusable vs client-specific seams.

## DAYS 31-60 — PROVE ONE CROSSING

| Objective                    | Actions                                                                                                   | Evidence                                      |
|------------------------------|-----------------------------------------------------------------------------------------------------------|-----------------------------------------------|
| Ship a thin production slice | Choose a bounded task with real workflow value, explicit human fallback and observable outcomes.          | Working increment in target environment.      |
| Install the contracts        | Document work, context, authority, evidence and run ownership alongside the implementation.               | Approved release posture and decision record. |
| Instrument the crossing      | Track task success, exceptions, human review, latency, cost and operational recovery.                     | Baseline vs production evidence.              |
| Test portability             | Identify what can be abstracted across OpenAI, Claude, Vertex/ open models and what is platform-specific. | Provider seam map and adaptation burden.      |

## DECISION AT DAY 60

Recommend one of four postures: release with controls; continue in shadow; human-first assist; hold and redesign. State the evidence and unresolved risk plainly.

## DAYS 61-90 — LEAVE LEVERAGE

---

| Objective                     | Actions                                                                                                           | Evidence                                                  |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| Operationalize ownership      | Confirm on-call/incident path, dashboards, cost unit, change policy, fallback and retirement conditions.          | Run contract signed by accountable owners.                |
| Package reusable learning     | Harvest evaluation cases, policy patterns, provider abstractions, workshop prompts and observability conventions. | Reusable assets with provenance and adaptation notes.     |
| Strengthen the pod            | Coach engineers and client counterparts through the reasoning, not only the artifact.                             | Client/ATC capability transfer and independent operation. |
| Shape the next portfolio move | Compare candidate use cases by value, readiness, authority risk, economics and reuse potential.                   | Scale, adapt or stop recommendations.                     |

## 90-DAY SCORECARD

---

Client outcome advanced · production slice accepted · authority and ownership explicit · metrics operating · reusable learning captured · client/ATC team able to run and improve the mechanism.

## DISCOVERY ASSUMPTIONS

---

This plan is a candidate hypothesis based on public role and company information. Engagement methods, tools and decision rights should be adapted to Accenture's actual delivery standards and the client's environment.
